1. Brainstorming & Ideation Phase

The brainstorming phase focused on identifying common issues that may occur while creating and managing Incident records in ServiceNow. Incident records require accurate and complete information for proper assignment, prioritization, routing, and resolution. However, when users manually enter the required information, there is a possibility of missing or incorrect data.

To address this problem, the idea of implementing **UI Policies and Client Scripts** was proposed. These ServiceNow features can dynamically control the behavior of fields based on specific conditions and user actions.

The main idea of the project was to use the **Impact** field as a condition for applying additional controls to an Incident. When the Impact is set to **High**, the system should automatically apply the required rules to maintain data consistency.

The proposed solution includes automatically setting the **Urgency** field to High, making the Urgency field read-only, validating the **Assigned To** field before saving the Incident, and preventing unauthorized changes to the **State** field through list editing.

The brainstorming process also considered the need for a lightweight and simple solution that could be implemented using standard ServiceNow configuration features. Therefore, UI Policies, UI Policy Actions, and Client Scripts were selected instead of introducing complex custom development.

The final project idea was to create a controlled Incident form that can automatically respond to user actions and prevent incomplete or incorrect Incident records from being submitted. This approach helps improve data quality, consistency, and user experience while demonstrating practical ServiceNow client-side functionality.

Proposed Key Features

- Apply additional controls when **Impact = High**.
- Automatically set **Urgency = High**.
- Make the **Urgency** field read-only for High Impact Incidents.
- Validate the **Assigned To** field before saving.
- Prevent direct **State** changes through list editing.
- Allow valid State changes through the normal Incident form.
- Reverse the applicable field behavior when the High Impact condition is removed.

Phase Outcome:
The brainstorming phase resulted in a clear project idea to use ServiceNow UI Policies and Client Scripts to improve Incident data accuracy and enforce business rules at the user-interface level.
